Jupyter Notebook

COMP 488 Large Language Models in Cyber

COMP-488 Final Project

Introduction

For the Final Project in this course I have decided to refine the LoRA training method to train Gemma 3 270m-instruc (B) 128k LoRA adapters on a practical choice for this setting because of the processing GPU power available and the time limit for the final project. In the project description notes, "Lofin tokens (and matrices) are decomposition of the original weight matrix into two low-rank matrices. Instead of training the full weight matrix, LoRA trains these smaller matrices, significantly reducing the number of parameters to be updated during training." Hard models to train allowing the Transformer Reinforcer library published by the Cutting Edge group at Cardiff University. The relevant GLU Gated relational decomposition classification task. I chose the relational decomposition of the difficulty it would pose to the model being trained. According to the paper, "Gated relational decomposition consistently challenging for the models, suggesting that the gated relational decomposition's underlying logic poses a hard task for models."

Background

Low-Rank Adaptation (LoRA) papers also mentioned models fine-tuning frequently adapted using Transformer reinforcement learning tools like adapter transfer. For instance, "RoA consists of updating all parameters, we compute:

$$W' = W_0 + BA$$

W' = updated weights, W_0 = frozen original weights, B = down-projection matrix, A = up-projection matrix.

where $B \in \mathbb{R}^{d \times r}$ and $A \in \mathbb{R}^{r \times k}$ with d = hidden dim, k = hidden dim, $r \ll \min(d, k)$.

B = trained dimensions, k = output dimensions, r = LoRA rank (typically 8, 16, 32, 64).

LoRA adapters apply and when practice to attention layers. This achieves a **100.0 parameter reduction** (261 × 10 parameters for Gemma 3) while maintaining performance, enabling efficient fine-tuning on consumer GPUs.

Implementation

Hardware

Component	Specification
Model	Apple MacBook Pro (Mac15,7)
CPU	10-core 4.5 GHz Apple M3
CPU Threads	10 threads (8 per core)
Mem RAM (Unified)	36 GB
Mem Bandwidth	150 GB/s
GPU	30 GB
GPU	30 GPU Apple GPU #940
GPU Memory	30 GB (MTL0M 30 GB)
Metal Support	Metal 4
Architecture	arm64
Kernels	Darwin 24.6.0

Software

Component	Specification
OS	Ventura (Core 24.1)
Python	3.11.9 (arm64)
Architecture	arm64
Distribution	conda-forge
Kernels	Darwin 24.6.0

Let's first setup up our working environment by running a small setup bash script:

```
source ./setup.sh
```

```
[1/7]Python 3.11.9(arm) (if necessary) Upgrade?
y
Python Upgrade: Upgrad Upgrad
[2/7]Upgrade pip
Upgrad Upgrad
[3/7]Upgrade setuptools, wheel
Upgrad Upgrade setuptools, wheel
[4/7]Install requirements.txt
Upgrad Upgrade setuptools, wheel, numpy, pandas, matplotlib, scikit-learn
[5/7]Install torch (MPS support)
Upgrad Upgrad torch (MPS support)
[6/7]Install transformers, datasets, peft, trl
Upgrad Upgrad transformers, datasets, peft, trl
[7/7]Verify installation

Upgrad Upgrade setuptools, wheel
```

Trade-offs Observed:

- **Model Expressiveness vs. Parameter Efficiency**: Higher rank increases the model's capacity to learn task-specific information, but also increases the number of trainable parameters. At r=16, the Gemma 4 E2B model maintains approximately 1-2M trainable parameters (compared to 9B total parameters) while still achieving significant performance gains.
- **Training Speed**: Lower ranks enable faster training and reduced memory consumption. With r=16, training could be performed efficiently on consumer GPUs with 48GB of memory, whereas larger ranks might require additional resources or batch size reduction.
- **Performance Plateau**: At r=16, the model achieved ~560× improvement in accuracy and ~220× improvement in F1 score, suggesting the rank was sufficient for learning emotion classification patterns without excessive parameter count.

Alternative Scenarios:

- **If r was 8**: We would have half the parameters (~500K-1M), faster training, but potentially reduced model expressiveness.
- **If r was 32**: We would have roughly double the parameters (~2-4M), potentially higher accuracy, but longer training time and risk of overfitting on the limited training set (approximately 3,300 training examples).

2. **Layer Selection Trade-off**

I applied LoRA adapters to **7 different layer types** across both the attention mechanism and feed-forward networks:

Trade-offs Observed:

- **Comprehensive Adaptation**: By targeting both attention layers (q_proj, k_proj, v_proj, o_proj) and feed-forward layers (gate_proj, up_proj, down_proj), the model can adapt its attention patterns AND its feed-forward transformations. This comprehensive approach likely contributed to the high parsing success rate (100% vs. 0.1% for the base model).
- **Parameter Redundancy**: Adapting all these layers increases trainable parameters substantially compared to adapting only attention layers. However, the emotion classification task benefits from having both mechanisms available for learning.
- **Training Convergence**: Adapting more layers may require slightly more training time and careful learning rate tuning, but it provides more flexibility for the model to learn task-specific patterns.

Alternative Scenarios:

- **Attention-only adapters** (q_proj, k_proj, v_proj, o_proj): Roughly 40-50% fewer parameters. Attention layers are often the most critical for NLP tasks, so this might achieve 85-90% of our current performance with faster training.
- **FFN-only adapters** (gate_proj, up_proj, down_proj): Might preserve expressiveness for this task but potentially reduce the model's ability to modify attention patterns, which could impact emotion understanding in context-dependent scenarios.

3. **LoRA Alpha (lora_alpha = 32) and Scaling**

The lora_alpha parameter controls the scaling of LoRA updates: $\text{output} = W_0 x + \frac{\text{lora_alpha}}{r} \cdot BAx$

Trade-offs Observed:

- **Update Magnitude**: With lora_alpha = 32 and r = 16, the effective scaling factor is 2.0, meaning LoRA updates have significant influence on the model's behavior.
- **Training Stability**: Higher alpha values can make training less stable if the learning rate is too high. However, with a conservative learning rate (2e-4), the model remained stable throughout 10 epochs.
- **Representation Preservation**: The moderate alpha value (32) strikes a balance between preserving the pre-trained knowledge (from the frozen base model) and adapting to the task.

Alternative Scenarios:

- **If lora_alpha = 8** (scaling factor = 0.5): More conservative updates. The model might struggle to sufficiently adapt to the emotion task, potentially requiring more training epochs.
- **If lora_alpha = 64** (scaling factor = 4.0): More aggressive updates. The model might adapt quickly but risk losing pre-trained knowledge or becoming unstable, especially with a small training set.

4. **LoRA Dropout (lora_dropout = 0.05) Regularization**

Dropout applied specifically to LoRA layers acts as regularization:

Trade-offs Observed:

- **Overfitting Prevention**: At 0.05 (5%), this conservative dropout rate provides mild regularization without excessive information loss.

Alternative Scenarios:

- **If lora_dropout = 0.1** (10%): More aggressive regularization, better suited for smaller datasets or higher overfitting risk. Might reduce training efficiency but improve generalization.
- **If lora_dropout = 0.0** (no dropout): Without regularization, the model might overfit on the small training set, showing good training performance but degraded validation/test performance.

5. **Overall Training Configuration Impact**

The combined choice of hyperparameters (r=16, alpha=32, 7 layer types, dropout=0.05) with 10 training epochs resulted in:

- **Efficient resource usage**: Training completed on a consumer-grade GPU (48GB)
- **Strong performance**: 39.20% accuracy vs. 0.07% base model (560× improvement)
- **Near-perfect parsing**: 100% vs. 0.1% successful prediction matching
- **Reasonable training time**: Approximately 10 epochs without excessive computation

6. **Lessons Learned for Hyperparameter Selection**

1. **Rank Selection**: Start with r ∈ {8, 16, 32} based on model size and task complexity. For Gemma 4 with emotion classification, r=16 proved sufficient.
2. **Layer Coverage**: Including both attention and feed-forward adapters was beneficial for structured output generation in this task.
3. **Task-Specific Tuning**: The challenge of emotion classification (sarcasm, context dependency) benefited from comprehensive layer adaptation.

Conclusion

The LoRA-tuned model successfully learns the emotion classification task with substantial improvements over the base model. The most impactful factor is the model's ability to generate structured, parseable outputs rather than random tokens. Per-class analysis reveals that closely related emotions (joy/optimism) remain challenging even after fine-tuning, suggesting that this task may require additional training data or techniques.
